Melanoma and other skin cancers: a guide for medical practitioners

Australia has among the highest rates of skin cancer in the world: 2 in 3 Australians will develop some form of skin cancer before the age of 70 years.

Skin cancer is divided into two main types

### Melanoma

Melanoma develops in the melanocytic (pigment-producing) cells located in the epidermis. Untreated, melanoma has a high risk for metastasis.

The most common clinical subtype is superficial spreading melanoma (SSM), making up 55–60% of all melanoma. SSM is most commonly found on the head and neck (per unit area). Other common sites are the trunk in males and lower extremities in females. However, SSM can develop on any part of the body, including parts not heavily exposed to ultraviolet (UV) radiation.

In NSW in 2013:
- There were more than 4,330 new cases of melanoma (10.3% of all cancer diagnoses) and over 540 deaths.
- Men over the age of 40, compared to women of similar age, are more than one and a half times more likely to be diagnosed with melanoma and two and a half times as likely to die from it.
- The lifetime risk of developing melanoma by age 85 years was one in 16.
- One in 16 of the hands and soles of the feet
- Acral lentiginous melanoma on the palms
- Subungual melanoma within the nail matrix.
- In 2012 in NSW, the mortality rate for older males aged:
  - 50-64 years was over twice that of females
  - 65-79 years was almost three times that of females
  - 80+ years was more than one and a half times that of females.

### Non-melanocytic skin cancer (NMSC)

- **Squamous cell carcinoma (SCC)** develops from keratinocytes in the epidermis and is associated with risk of metastasis. Overall, SCC is most commonly found on the face, particularly the lip region, ears, nose, cheek and eyelid, and then on the neck, dorsa of hands and forearms. In males, SCC is commonly found on the head and neck, and in females, it is commonly found on the upper limbs, followed by the head and neck. Many SCCs arise from premalignant actinic keratoses.
- **Basal cell carcinoma (BCC)** also develops from keratinocytes in the epidermis and is the most frequently diagnosed cancer in Australians. In both sexes, BCC is most commonly found on the face (the eyelid, lip and nasolabial fold), followed by ears, nose and cheek. In males, BCC is common on the neck, back and shoulders. In females, BCC is common on the neck, shoulders and outer arms.
- In 2010, it was estimated that 148,610 cases of NMSC were diagnosed in NSW and there were 145 deaths.

### Causes of melanoma and other skin cancers

- Unprotected exposure to UV radiation remains the single most important lifestyle risk factor for melanoma and other skin cancers.
- UV-A and UV-B radiation contribute to skin damage, premature ageing of the skin and skin cancer.
- Melanoma and BCC are associated with the amount and pattern of sun exposure, with an intermittent pattern carrying the highest risk. UV exposure in adulthood as well as in childhood contributes to BCC and melanoma risk.
- Premalignant actinic keratoses and SCC are associated with the total amount of sun exposure accumulated over a lifetime.
- Other risk factors for NMSC can include exposure to some chemicals (e.g. arsenic); radiation therapy and psoralen (PUVA) treatment for psoriasis; immunosuppressive therapy; and some rare genetic conditions predisposing people to skin cancer.

### Risk factors for melanoma

- Multiple naevi (moles)
- Multiple dysplastic naevi
- Personal or family history of melanoma
- Increasing age
- High levels of intermittent sun exposure (e.g. during outdoor recreation or sunny holidays)
- Personal history of NMSC
- Fair skin that burns easily, freckles and does not tan
- Having fair or red hair and blue or green eyes
- Immune suppression and/or transplant recipients.

### Gender

Men are more likely to develop and die from melanoma than women. Mortality from melanoma rises for males from 40 years and increases with age. Men over the age of 40, compared to women of similar age, are more than one and a half times more likely to be diagnosed with melanoma and two and a half times as likely to die from it.

In 2012 in NSW, the mortality rate for older males aged:
- 50-64 years was over twice that of females
- 65-79 years was almost three times that of females
- 80+ years was more than one and a half times that of females.

### Melanoma in Indigenous Australians and non-Caucasian patients

The incidence of melanoma in Indigenous Australians is low. For the period 2008–2012, twenty-two Indigenous Australians died from melanoma, representing 0.4% of all melanoma deaths. For the same period, there were 7,300 deaths from melanoma overall. The incidence of melanoma in non-Caucasians is also low. However, non-Caucasians are more likely to experience delayed diagnosis and have poorer clinical prognosis compared to Caucasians.

### Non-Caucasians tend to develop clinical melanoma subtypes rare in Caucasian populations:

- Acral lentiginous melanoma on the palms of the hands and soles of the feet
- Subungual melanoma within the nail matrix.
Melanoma diagnosis

Superficial spreading melanoma (SSM)
Melanoma can develop in pre-existing moles in the skin or, more commonly, de novo.
- SSM is the most common form of melanoma.
- SSM can appear as a new spot, or an existing spot, freckle or mole that changes size, colour or shape.
- A patient diagnosed with SSM is at increased risk of new primary melanomas (relative risks ranging above 10).
(See examples on last page)

Nodular melanoma (NM)
This is a highly dangerous form of melanoma that grows and can metastasise quickly, and differs from SSM in appearance.
- NM has little radial growth within the epidermis but penetrates vertically into the dermis early.
- NM can develop de novo in normal-appearing skin, or within another type of melanoma.
- NM is more likely to be symmetrical and uniform in colour (red, pink, brown or black), is more frequently lighter coloured than SSM, and feels firm to the touch.
- Over time, NM may develop a crusty surface that bleeds easily.
- NM develops most commonly on the head and neck, in sun-damaged skin and in older people, particularly men.
- Approximately 10–15% of total melanomas diagnosed are NM.
(See examples on last page)

Lentigo Maligna (LM)
A slow growing form of melanoma in situ that can be difficult to recognise. LM can resemble a freckle and develops in heavily sun-damaged older skin, especially on the head and neck. Margin determination can be challenging and there is more frequent local recurrence than other types of melanoma. Incidence of LM is increasing.

The ABCD(E) acronym can help distinguish an SSM from a normal mole:
A Asymmetry: the lesion is irregular in shape or pattern.
B Border: the border or outline of a melanoma is usually irregular.
C Colour: there is variation in colour within the lesion.
D Diameter: the lesion is usually greater than 6 mm across. However, suspect lesions of smaller diameter should also be investigated.
E Evolving: the lesion changes over time (size, shape, surface, colour, symptoms e.g. itch).

The ABCD(E) acronym cannot be used to aid diagnosis of NM but the following features – EFG – can be of help:
E Elevated: the lesion can appear as a small, round and raised lump on the skin. Colour may be uniform throughout the lesion and may be black, brown, pink or red.
F Firm: the lesion feels firm to the touch.
G Grows: a nodule that has been growing progressively for more than a month should be assessed as a matter of urgency.

Diagnosis tools
- Dermoscopy uses a hand-held magnifying device combined with either the application of a liquid between the transparent plate of the device and the skin, or the use of cross-polarised light. It allows the visualisation of diagnostic features of skin lesions that are not seen with the naked eye.
- Dermoscopy increases diagnostic accuracy, confidence in diagnosis and reduces unnecessary excision of benign lesions. Training and utilisation of dermoscopy is recommended for clinicians routinely examining pigmented skin lesions.
- Sequential digital dermoscopy imaging (SDDI) involves the assessment of successive dermoscopic images to allow the detection of suspicious dermoscopic change in melanomas that lack dermoscopic evidence of melanoma at a particular time.
- Total body photography allows the detection of suspicious change and is useful in high-risk patients or patients with dysplastic nevi syndrome.
- In vivo confocal microscopy allows non-invasive “optical biopsy” with the visualisation of the morphology and organisation of the cells in depth of the skin. It is useful for difficult diagnoses and margins (i.e. amelanotic melanoma, LM) in specialised centres.

Biopsy and excision for melanoma or suspicious naevi
- Complete excision biopsy with a 2 mm margin is recommended.
- Partial biopsies (i.e. punch biopsies and shave excisions) can be less accurate than excisional biopsy and should be performed by trained practitioners only.
- If a thick SSM or NM is suspected, refer patient to a dermatologist, a multidisciplinary melanoma unit or a surgeon with an interest in melanoma as a matter of urgency.

If nodular or thick melanoma is suspected, diagnosis should not be delayed, and urgent referral to a dermatologist, melanoma unit or immediate excision is recommended.

Any lesion that displays the EFG features over a period of more than one month should be investigated.
Treatment for melanoma

Selecting appropriate primary treatment will depend on the Breslow thickness (vertical depth) of the tumour as measured and reported by tissue pathologists. Breslow thickness is measured in the Tumour, Node, Metastases (TNM) staging system for melanoma tumours and is measured using the following system:

<table>
<thead>
<tr>
<th>(pTis) Melanoma in situ</th>
<th>5 mm to 10 mm clearance</th>
</tr>
</thead>
<tbody>
<tr>
<td>(pT1) Melanoma cells reach the upper part of the dermis.</td>
<td>1 cm clearance</td>
</tr>
<tr>
<td>(pT2) Melanoma cells reach the upper part of the dermis.</td>
<td>1–2 cm clearance</td>
</tr>
<tr>
<td>(pT3) Melanoma cells reach deeper into the dermis.</td>
<td>1–2 cm clearance</td>
</tr>
<tr>
<td>(pT4) Melanoma &gt;4.0 mm</td>
<td>2 cm clearance</td>
</tr>
</tbody>
</table>

Note: Evidence for optimal excision clearance for melanoma 2–4 mm thick is unclear. The Clinical Practice Guidelines recommend it may be desirable to take a wider margin depending on tumour site and surgeon/patient preference.

The T1-T4 (Primary Tumour Thickness) classification is further divided into groups depending on presence of ulceration (a or b).

- The N classification (Regional Lymph Nodes) is divided into a, b, and c for presence of cancer cells in the lymph nodes.
- The M classification (Distant Metastasis): ranges from no evidence of distant metastasis (MX) to all visceral/any distant metastasis (M1c).

Treatment is based on the 5 stages (0 to 4) of tumour thickness (TNM classification) and involves the surgical removal of the melanoma. The recommended margins of excision are based on the Tis-T4 classification as follows:

<table>
<thead>
<tr>
<th>Staging</th>
<th>Margin</th>
</tr>
</thead>
<tbody>
<tr>
<td>pTis</td>
<td>5 mm to 10 mm clearance</td>
</tr>
<tr>
<td>pT1</td>
<td>1 cm clearance</td>
</tr>
<tr>
<td>pT2</td>
<td>1-2 cm clearance</td>
</tr>
<tr>
<td>pT3</td>
<td>1-2 cm clearance</td>
</tr>
<tr>
<td>pT4</td>
<td>2 cm clearance</td>
</tr>
</tbody>
</table>

Oncology treatments
- Adjvant treatment in high-risk loco-regional melanoma. Interferon is still a standard of care for adjuvant treatment, however it is not widely used given its high risk-benefit ratio. It is expected to be superseded as adjuvant trials using newer agents are completed.

Systemic treatments in metastatic or inoperable melanoma. One year survival in patients with visceral metastatic disease has risen from 30% to over 70% when treated on phase III clinical trials and has resulted in the approval of >5 new drug therapies on the PBS. This is due to two key developments:

- Targeted therapies with the inhibition of the mitogen activated protein kinase pathway (BRAF and MEK inhibitor) in V600 BRAF mutant melanoma. These therapies are now used mostly in combination, in order to achieve greater efficacy and reduced side effects (in particular the development of squamous cell carcinomas and other minor skin disruptions such as acne, warty lesions and hair follicle changes and sensitivity to UVA).

- Immunological therapies Modulate host anti-tumour immune responses via inhibitors of immune checkpoints on T cells, namely the cytotoxic T lymphocyte associated protein 4 (CTLA-4) receptor and the programmed death 1 (PD-1) receptor.

Follow-up for melanoma

Due to the risk of tumour recurrence and new primary melanomas, all patients require routine follow-up, the frequency of which will depend on the stage (0-4) of the primary tumour at time of diagnosis:

- 6-monthly intervals for 5 years then yearly for patients with stage I (localised) disease
- 3-monthly or 4-monthly intervals for 5 years and then yearly (with ultrasound examination of regional lymph nodes) for patients with stage II or III disease
- 3 monthly intervals or according to trial protocol for patients with stage IV disease.

In Australia, up to 75% of patients detect their own recurring melanomas. Patients should be educated on recognising changes in their skin, have a professional full skin examination as deemed appropriate, and have further testing as required.

The Clinical Practice Guidelines for the Management of Melanoma in Australia and New Zealand 2008, are currently under review. Recommendations relating to frequency of routine follow-up for melanoma patients may change.
Non-melanoma skin cancer (NMSC) diagnosis

Squamous cell carcinoma (SCC)
- SCC can spread to other parts of the body if not treated. Lesions on the face and scalp, histologically aggressive and/or larger tumours, and tumours arising in immune-suppressed individuals have a higher risk of metastasis.
- SCC appears as a thickened, red, scaly nodule that may bleed and ulcerate over time.
- SCC grows over a period of weeks to months.
(See more examples on last page)

Basal cell carcinoma (BCC)
- BCC is the most common and least dangerous form of skin cancer.
- BCC appears as a well-defined lump or scaly area that is red or pearly in colour.
- BCC may bleed or become ulcerated early on, then heal and break down again.
- BCC usually grows relatively slowly.
- High-risk BCC subtypes (eg micronodular, infiltrating or morpheaic) and BCCs in immune suppressed individuals tend to have higher rates of recurrence after treatment.
(See more examples on last page)

Treatment for NMSC

Treatment options for NMSC include:
- surgical excision of the tumour and surrounding tissue
- radiotherapy
- curettage
- diathermy/electrodessication.

For biopsy-proven superficial lesions:
- cryotherapy
- application of topical agents (imiquimod cream, 5-fluorouracil cream, photodynamic therapy).

In general, the choice of treatment will depend on:
- tumour size
- thickness and grade
- aetiology
- histological features
- anatomic site
- patient preference and medical comorbidities.

Follow-up for NMSC

Frequency of follow-up of patients treated for NMSC for evidence of recurrence, metastasis and/or any new primary skin cancers will depend on histological clearance and risk level of the tumour, and on number of previous skin cancers. Patients should be educated on recognising changes in their skin (including examination of draining lymph nodes for patients with SCC) and have a professional full skin examination as deemed appropriate.

Screening for melanoma and NMSC

There is no evidence demonstrating that population-based screening for melanoma and NMSC is effective in reducing morbidity or mortality, and it is not recommended. Skin surveillance is recommended for patients identified to be at high risk of melanoma and NMSC, including patients with a previous diagnosis of melanoma.

Skin self-examination (SSE) for melanoma and NMSC

Approximately 50% of melanomas are detected by the patient. There is no specific SSE technique or recommended frequency of self-examination that has been shown to reduce morbidity, however, regular skin examination may increase the probability of detecting skin cancer at an early and treatable stage.

Patients at high risk for melanoma should:
- be taught to self-screen (including examination of draining lymph nodes) and recognise suspicious lesions
- have a full body examination with a clinician every 6 to 12 months.

Patients treated for NMSC should:
- be taught to self-screen and recognise changes to their skin
- have a full body examination with a clinician every 12 months or more frequently for patients at highest risk.

For the general population, the Australasian College of Dermatologists recommends that people examine their skin 4 times a year or as often as recommended by their medical practitioner.
